

The "Reticular Grunt" Test for Traumatic Reticulo-peritonitis

Eric I. Williams, F.R.C.V.S., M.S.
Department of Medicine and Surgery
College of Veterinary Medicine
Oklahoma State University
Stillwater, Okla. 74074

Previous observations by the author have shown that the cycle of reticulo-ruminal motility in normal adult cattle occurs in two phases:

1. A contraction of the reticulum, followed by a contraction of the rumen. Eructation of ruminal gases does *not* occur at this stage because the cardia region is flushed with ingesta.
2. Following relaxation of the reticulum and rumen, an independent contraction of the rumen occurs. This contraction is *accompanied by eructation*. Relaxation of the reticulum and rumen completes the cycle.

These two phases can easily be identified by observing the left flank where the dorsal rumen lies directly below the skin, muscles and peritoneum. Contractions of the rumen can easily be identified by observing or palpating this area. Immediately before eructation, the animal holds its breath and the act of eructation can be observed and the gurgling sound can easily be identified. The wave of eructation traveling up the esophagus can usually be observed in the neck.

The two phases of reticulo-ruminal motility usually occur on a 1:1 ratio. A reticulo ruminal contraction *without* eructation followed by a ruminal contraction *with* eructation. Variations in this ratio occur, depending on the degree of fullness of the rumen, type of feed etc.

The Reticular Grunt Test

Penetration of the wall of the reticulum by a sharp

object causes inflammation in the peritoneum covering this area. The animal will thus show evidence of pain, in the form of a grunt, during contractions of the reticulum.

The "reticular grunt" test is based on the correlation of pain with contractions of the reticulum. Since these contractions occur in conjunction with ruminal contractions, the clinician should carefully observe the animal and listen for a short stabbing grunt during these *non-eructating* ruminal contractions. The astute clinician can also detect other evidence of pain at this time, when the animal often shows discomfort by alternative slight lifting of the forefeet, (gentle "shuffling" of the forefeet).

Since some positive cases only show a mild grunt, the clinician will be more likely to detect it by carefully observing the left costal arch. The animal will hold its breath just before emitting a grunt.

This test was found to be reliable by the author in a study of 100 cases. It must be emphasized, however, that it can only be used in early cases of traumatic reticulo-peritonitis. Due to the remarkable resistance of the bovine peritoneum to infection, etc., grunting may not be detected 48 hours or so after the onset of symptoms. Ingestion of food in such cases may cause grunting.

The test is recommended as an exercise in 20/20 clinical vision, based on the clinical interpretation of fore-stomach motility.

One out of five dead before six months.

You don't have to live with that... with Diamond's "Calf Savers".

Statistics prove that as many as one out of five calves die during the first six months of their life. And the primary cause of death? . . . Scours and related respiratory side-effects.

You can reduce that number significantly and eliminate a lot of needless calf losses with one of these "calf-saving" products from Diamond Laboratories.

■ *For calf pneumonia*

SEROGEN® LA . . . (Corynebacterium Pasteurella Antiserum, Bovine Origin, Concentrate) works against three bacterial pathogens—*Pasteurella Multocida*, *Pasteurella hemolytica* and *Corynebacterium pyogenes*—the bacteria most commonly associated with calf pneumonia. SEROGEN LA assists in preventing virulent pneumonia that causes death and low-level respiratory infections that hinder performance. SEROGEN LA is derived from cattle which have been repeatedly hyperimmunized with the viruses of IBR, BVD, and PI₃, in addition to *C. pyogenes*, *P. multocida* and *P. hemolytica*.

■ *For calf bacterial pneumonia and scours*

CALF SCOURS BOLUSES . . . (Oxytetracycline with Neomycin, Kaolin, Vitamin A, D₃ and Electrolytes) contains a combination of potent antibiotic drugs that acts both in the intestines and in the bloodstream, providing therapeutic action against scours

and secondary bacterial infections. Each Scours Bolus contains kaolin, providing a protective coating that adsorbs bacterial toxins already in the intestines of scouring calves. The addition of Vitamins A, D₃ and electrolytes offers a potent combination that few calf scour boluses contain.

■ *For dehydration due to scours*

ION-AID® . . . (water soluble Oral Electrolyte Powder with Glycine and Glucose) attacks the most devastating problem associated with scours — dehydration. ION-AID, a nutrient, represents a different approach in handling both diarrhea and dehydration in young calves. It achieves rapid rehydration by utilizing the physiological mechanisms of water and electrolyte transport. The amino acid glycine and carbohydrate glucose in ION-AID are orally administered and conveniently packaged for use.
